ABSTRACT

A method and apparatus are disclosed for execution capacity among tasks executing in a real-time computing The present invention extends RMA techniques for system. characterizing system timing behavior and designing real-time A high priority task having hard deadlines is paired with a lower priority task having soft deadlines. overload condition, the higher priority task can dynamically borrow execution time from the execution capacity of the lower priority task without affecting the schedulability of the rest of The higher priority task is bolstered the system. proportion to the capacity borrowed from the lower priority task, so that the combined utilization of the two tasks remains The period of the degraded task is increased to constant. compensate for the execution time that was loaned to the higher priority task. In addition, the priority of the lower priority task is modified to match the new period.
